(57) **ABSTRACT**

The disclosure includes a system and method for providing zone information to a user. The system includes a processor and a memory storing instructions that when executed cause the system to: receive data describing a current location and a travel speed associated with a user; determine a travel status associated with the user based on the current location and the travel speed; create a zone of relevance for the user based on the travel status, the zone of relevance including one or more regions with each region being mapped to one or more regional circles; generate one or more queries for the zone of relevance; retrieve one or more query results that match the zone of relevance using the one or more queries; process the one or more query results to generate zone information relevant to the user; and provide the zone information to the user.

SYSTEM FOR PROVING PROACTIVE ZONE INFORMATION

BACKGROUND

The specification relates to providing zone information to a user. In particular, the specification relates to a navigation system for providing proactive zone information to a user based on a zone of relevance.

A user may want to know information ahead on a road before traveling down the road. In some examples, a user can listen to a traffic radio in order to obtain traffic information. However, the traffic radio may not provide traffic information relevant to the user's journey.

In some examples, a user can use a navigation system such as a global positioning system (GPS) to obtain information related to the user's journey. Existing navigation systems require the user to input a destination, calculate a route for the destination and then deliver information related to the calculated route to the user. However, the user may not want to input a destination to a navigation system when taking a journey. The user may not follow a route provided by the navigation system. The user may decide to go to a new destination in the middle of travel. In these cases, existing navigation systems fail to provide the user with information associated with the user's journey.

SUMMARY

According to one innovative aspect of the subject matter described in this disclosure, a system for providing zone information to a user includes a processor and a memory storing instructions that, when executed, cause the system to: receive data describing a current location and a travel speed associated with a user; determine a travel status associated with the user based on the current location and the travel speed; create a zone of relevance for the user based on the travel status, the zone of relevance including one or more regions with each region being mapped to one or more regional circles; generate one or more queries for the zone of relevance; retrieve one or more query results that match the zone of relevance using the one or more queries; process the one or more query results to generate zone information relevant to the user; and provide the zone information to the user.

In general, another innovative aspect of the subject matter described in this disclosure may be embodied in methods that include: receiving data describing a current location and a travel speed associated with a user; determining a travel status associated with the user based on the current location and the travel speed; creating a zone of relevance for the user based on the travel status, the zone of relevance including one or more regions with each region being mapped to one or more regional circles; generating one or more queries for the zone of relevance; retrieving one or more query results that match the zone of relevance using the one or more queries; processing the one or more query results to generate zone information relevant to the user; and providing the zone information to the user.

Other aspects include corresponding methods, systems, apparatus, and computer program products for these and other innovative aspects.

These and other implementations may each optionally include one or more of the following features. For instance, the operations include: receiving data describing a travel direction associated with the user; receiving data describing a local map associated with the current location; and matching the current location to the local map to determine a road type.

For instance, the features include: determining a regional angle and a regional length for each region based on the travel status; generating the one or more regions based on the regional angle and the regional length; determining one or more circle centers and one or more radii for the one or more regional circles in each region; matching each region to the one or more corresponding regional circles that are determined by the one or more circle centers and the one or more radii; determining the zone of relevance including the one or more regions with each region being mapped to the one or more corresponding regional circles; the one or more queries including one or more circle queries with each circle query corresponding to one of the one or more regional circles in each region; filtering the one or more query results to remove duplicate data; filtering the one or more query results to remove data related to a direction opposite to a travel direction associated with the user; combining the one or more filtered query results to generate the zone information relevant to the user; the travel status being further determined based on the road type and the travel direction; the zone of relevance being configured based on at least one of a travel direction and a road type; and the one or more regions including a front region, a left region and a right region.

The present disclosure may be particularly advantageous in a number of respects. First, the system creates a zone of relevance for a user based on the user's travel status that includes one or more of a current location, a travel speed, a road type and one or more travel preferences associated with the user. The system dynamically configures the zone of relevance to match the latest travel status associated with the user. Second, the system is capable of providing proactive zone information ahead of a user's journey to the user based on the zone of relevance. The system dynamically updates the relevant zone information to match the user's travel status. Third, the system does not require a user to input a destination and does not need to calculate a route before providing zone information to the user. The system is capable of providing zone information relevant to the user without requiring the user to provide an input.

BRIEF DESCRIPTION OF THE DRAWINGS

The disclosure is illustrated by way of example, and not by way of limitation in the figures of the accompanying drawings in which like reference numerals are used to refer to similar elements.

FIG. **1** is a block diagram illustrating an example system for providing zone information to a user.

FIG. **2** is a block diagram illustrating an example of a navigation application.

FIG. **3** is a flowchart of an example method for providing zone information to a user.

FIGS. **4**A and **4**B are flowcharts of another example method for providing zone information to a user.

FIG. **5** is a flowchart of an example method for matching a region with one or more regional circles.

FIGS. **6**A-**6**C are graphic representations illustrating a process to match a region with one or more regional circles according to some embodiments.

FIGS. **7**A-**7**F are graphic representations illustrating various zones of relevance according to some embodiments.

DETAILED DESCRIPTION

Overview

FIG. **1** illustrates a block diagram of a system **100** for providing zone information to a user according to one

embodiment. The illustrated system **100** includes a navigation server **101**, one or more client devices **115**, a mobile computing system **135** and one or more data servers **120**. The entities of the system **100** are communicatively coupled via a network **105**. In FIG. **1** and the remaining figures, a letter after a reference number, e.g., "**115***a*," represents a reference to the element having that particular reference number. A reference number in the text without a following letter, e.g., "**115**," represents a general reference to instances of the element bearing that reference number.

The network **105** can be a conventional type, wired or wireless, and may have numerous different configurations including a star configuration, token ring configuration or other configurations. Furthermore, the network **105** may include a local area network (LAN), a wide area network (WAN) (e.g., the Internet), and/or other interconnected data paths across which multiple devices may communicate. In some embodiments, the network **105** may be a peer-to-peer network. The network **105** may also be coupled to or includes portions of a telecommunications network for sending data in a variety of different communication protocols. In some embodiments, the network **105** includes Bluetooth communication networks or a cellular communications network for sending and receiving data including via short messaging service (SMS), multimedia messaging service (MMS), hypertext transfer protocol (HTTP), direct data connection, WAP, email, etc. Although FIG. **1** illustrates one network **105** coupled to the navigation server **101**, the one or more client devices **115**, the mobile computing system **135** and the one or more data servers **120**, in practice one or more networks **105** can be connected to these entities.

In one embodiment, the navigation application **109***a* is operable on the navigation server **101**, which is coupled to the network via signal line **104**. The navigation server **101** can be a hardware server that includes a processor, a memory and network communication capabilities. In some embodiments, the navigation server **101** sends and receives data to and from one or more of the data servers **120***a*, **120***n*, the client devices **115***a*, **115***n* and the mobile computing system **135**. The navigation server **101** also includes a storage device **143**, which is described below in more detail. Although FIG. **1** illustrates one navigation server **101**, the system **100** can include one or more navigation servers **101**.

In another embodiment, the navigation application **109***b* is operable on a client device **115***a*, which is connected to the network **105** via signal line **108**. In some embodiments, the client device **115***a*, **115***n* sends and receives data to and from one or more of the navigation server **101**, the data servers **120***a*, **120***n* and the mobile computing system **135**. The client device **115***a*, **115***n* is a computing device that includes a memory and a processor, for example a laptop computer, a desktop computer, a tablet computer, a mobile telephone, a personal digital assistant (PDA), a mobile email device or any other electronic device capable of accessing a network **105**. In some embodiments, the client device **115***a* includes a browser **177** for accessing online services and a storage device **145** for storing data accessible by the client device **115***a*. The storage device **145** is described below in more detail. In the illustrated embodiment, the user **125***a* interacts with the client device **115***a* via signal line **110**. The client device **115***n* is communicatively coupled to the network **105** via signal line **175**. The user **125***n* interacts with the client device **115***n* via signal line **114**. Although FIG. **1** illustrates two client devices **115**, the system **100** can include one or more client devices **115**.

In some instances, the navigation application **109***b* acts in part as a thin-client application that may be stored on the client device **115***a*, **115***n* and in part as components that may be stored on one or more of the navigation server **101** and the mobile computing system **135**. For example, the navigation server **101** stores zone information relevant to a user in the storage device **143** and generates graphical data for providing a user interface that depicts the zone information to the user. The navigation application **109***b* sends instructions to the browser **177** to present the user interface on a display device (not shown) coupled to the client device **115**.

In yet another embodiment, the navigation application **109***c* is operable on a mobile computing system **135**, which is coupled to the network **105** via signal line **134**. In some embodiments, the mobile computing system **135** sends and receives data to and from one or more of the navigation server **101**, the data servers **120***a*, **120***n* and the client devices **115***a*, **115***n*. The mobile computing system **135** is any computing device that includes a memory and a processor. In one embodiment, the mobile computing system **135** is one of a vehicle, an automobile, a bus, a bionic implant or any other mobile system with non-transitory computer electronics (e.g., a processor, a memory or any combination of non-transitory computer electronics). In one embodiment, the mobile computing system **135** includes a laptop computer, a tablet computer, a mobile phone or any other mobile device including a processor and a memory. In some embodiments, the mobile computing system **135** includes a storage device **144** which is described below in more detail. In one embodiment, a user **125** interacts with the mobile computing system **135**. For example, a user **125** can be a driver driving a vehicle or a passenger seating in a vehicle. Although FIG. **1** illustrates one mobile computing system **135**, the system **100** can include one or more mobile computing systems **135**.

The navigation application **109** is code and routines for providing zone information to a user. In some implementations, the navigation application **109** can be implemented using hardware including a field-programmable gate array (FPGA) or an application-specific integrated circuit (ASIC). In some other implementations, the navigation application **109** can be implemented using a combination of hardware and software. In some implementations, the navigation application **109** may be stored in a combination of the devices and servers, or in one of the devices or servers. The navigation application **109** is described below in more detail with reference to FIGS. **2-5**.

The storage devices **143**, **144** and **145** each can be a non-transitory memory that stores data for providing the functionality described herein. The storage devices **143**, **144** and **145** each may be a dynamic random access memory (DRAM) device, a static random access memory (SRAM) device, flash memory or some other memory devices. In some embodiments, the storage devices **143**, **144** and **145** each also include a non-volatile memory or similar permanent storage device and media including a hard disk drive, a floppy disk drive, a CD-ROM device, a DVD-ROM device, a DVD-RAM device, a DVD-RW device, a flash memory device, or some other mass storage device for storing information on a more permanent basis.

In one embodiment, the storage devices **143**, **144** and **145** each store one or more of: data describing historical travel data associated with a user (e.g., start locations, destinations, routes, travel durations, etc., associated with a user's past journeys); data describing one or more travel preferences associated with a user; data describing a current location associated with a user; data describing a travel speed associated with a user (e.g., a speed of a vehicle that a user is driving or seating in); data describing navigation instructions (e.g., routes from a first location to a second location); data describing a zone of relevance associated with a user; and zone

information relevant to a user, etc. The zone of relevance and zone information are described below in more detail with reference to FIG. **2**. The storage devices **143**, **144** and **145** may store other data for providing the functionality described herein.

Example travel preferences include, but are not limited to, a user's driving preference (e.g., choosing a route without any highway, choosing a route with a fastest travel time, etc.) and a user's configuration preference for a zone of relevance (e.g., a number of regions, a size for each region, a shape for each region, an angle offset, a regional angle, a regional length, etc., configured by a user).

The data server **120***a* can be a hardware server that includes a processor, a memory and network communication capabilities. In some embodiments, the data server **120***a* sends and receives data to and from one or more of the navigation server **101**, the client devices **115***a*, **115***n* and the mobile computing system **135**. In the illustrated embodiment, the data server **120***a* is communicatively coupled to the network **105** via signal line **121**. The data server **120***n* is communicatively coupled to the network **105** via signal line **123**. Although FIG. **1** includes two data servers **120***a*, **120***n*, the system **100** may include one or more data servers **120**.

In one embodiment, the data server **120***a* acts as a data source that provides various information to the navigation application **109**. For example, the data server **120***a* can be a traffic provider that provides traffic information, road construction information, accident reports, etc., to the navigation application **109**. In another example, the data server **120***a* provides data describing locations of refreshment services, gas stations, tourist places, events (e.g., sport events), weather conditions, etc., to the navigation application **109**.

In the illustrated embodiment, the data server **120***a* includes a mapping application **122**. The mapping application **122** can be code and routines for processing a request or a query received from the navigation application **109**. In some embodiments, the mapping application **122** receives a request for a map from the navigation application **109**. For example, the navigation application **109** sends a request for a local map to the mapping application **122**. The mapping application **122** processes the request and returns data describing the local map to the navigation application **109**.

In some embodiments, the mapping application **122** is capable of retrieving information relevant to a geographic area. For example, the mapping application **122** retrieves traffic information, weather information or other information related to a circular geographic area having a given radius and a given center point. In some instances, the mapping application **122** receives a query specifying a zone of relevance from the navigation application **109**, generates a query result matching the zone of relevance and sends the query result to the navigation application **109**. In some instances, the mapping application **122** receives one or more circle queries from the navigation application **109**, generates one or more query results matching the one or more circle queries and sends the one or more query results to the navigation application **109**. The circle queries and the query results are described below with reference to FIG. **2**.

Example Navigation Application

Referring now to FIG. **2**, an example of the navigation application **109** is shown in more detail. FIG. **2** is a block diagram of a computing device **200** that includes a navigation application **109**, a processor **235**, a memory **237**, a communication unit **241**, an input/output device **243** and a storage device **245** according to some embodiments. The components of the computing device **200** are communicatively coupled by a bus **220**. The input/output device **243** is communicatively coupled to the bus **220** via signal line **230**. In one embodiment, the computing device **200** is a navigation server **101**. In another embodiment, the computing device **200** is a client device **115**. In yet another embodiment, the computing device **200** is a mobile computing system **135**.

The processor **235** includes an arithmetic logic unit, a microprocessor, a general purpose controller or some other processor array to perform computations and provide electronic display signals to a display device. The processor **235** is coupled to the bus **220** for communication with the other components via signal line **222**. Processor **235** processes data signals and may include various computing architectures including a complex instruction set computer (CISC) architecture, a reduced instruction set computer (RISC) architecture, or an architecture implementing a combination of instruction sets. Although FIG. **2** includes a single processor **235**, multiple processors **235** may be included. Other processors, operating systems, sensors, displays and physical configurations are possible.

The memory **237** stores instructions and/or data that can be executed by the processor **235**. The memory **237** is coupled to the bus **220** for communication with the other components via signal line **224**. The instructions and/or data may include code for performing the techniques described herein. The memory **237** may be a dynamic random access memory (DRAM) device, a static random access memory (SRAM) device, flash memory or some other memory device. In some embodiments, the memory **237** also includes a non-volatile memory or similar permanent storage device and media including a hard disk drive, a floppy disk drive, a CD-ROM device, a DVD-ROM device, a DVD-RAM device, a DVD-RW device, a flash memory device, or some other mass storage device for storing information on a more permanent basis.

In the illustrated embodiment, the communication unit **241** is communicatively coupled to the bus **220** via signal line **226**. The communication unit **241** transmits and receives data to and from one or more of the navigation server **101**, the mobile computing system **135**, the client device **115** and the data server **120**. In some implementations, the communication unit **241** includes a port for direct physical connection to the network **105** or to another communication channel. For example, the communication unit **241** includes a USB, SD, CAT-5 or similar port for wired communication with the client device **115**. In some implementations, the communication unit **241** includes a wireless transceiver for exchanging data with the client device **115** or other communication channels using one or more wireless communication methods, including IEEE 802.11, IEEE 802.16, BLUETOOTH®, dedicated short-range communications (DSRC) or another suitable wireless communication method.

In some implementations, the communication unit **241** includes a cellular communications transceiver for sending and receiving data over a cellular communications network including via short messaging service (SMS), multimedia messaging service (MMS), hypertext transfer protocol (HTTP), direct data connection, WAP, e-mail or another suitable type of electronic communication. In some implementations, the communication unit **241** includes a wired port and a wireless transceiver. The communication unit **241** also provides other conventional connections to the network **105** for distribution of files and/or media objects using standard network protocols including TCP/IP, HTTP, HTTPS and SMTP, etc.

The storage device **245** can be a non-transitory memory that stores data for providing the functionality described herein. The storage device **245** may be a dynamic random access memory (DRAM) device, a static random access

memory (SRAM) device, flash memory or some other memory devices. In some embodiments, the storage device **245** also includes a non-volatile memory or similar permanent storage device and media including a hard disk drive, a floppy disk drive, a CD-ROM device, a DVD-ROM device, a DVD-RAM device, a DVD-RW device, a flash memory device, or some other mass storage device for storing information on a more permanent basis.

In the illustrated embodiment, the storage device **245** is communicatively coupled to the bus **220** via signal line **228**. In one embodiment, the storage device **245** represents the storage device **143** in the navigation server **101**. In another embodiment, the storage device **245** represents the storage device **144** in the mobile computing system **135**. In yet another embodiment, the storage device **245** represents the storage device **145** in the client device **115**.

In the illustrated embodiment, the navigation application **109** includes a controller **202**, a map module **204**, a status module **206**, a zone creator **207**, a search module **208**, a processing module **210**, a presentation module **212** and a user interface module **214**. These components of the navigation application **109** are communicatively coupled via the bus **220**.

The controller **202** can be software including routines for handling communications between the navigation application **109** and other components of the computing device **200**. In some implementations, the controller **202** can be a set of instructions executable by the processor **235** to provide the functionality described below for handling communications between the navigation application **109** and other components of the computing device **200**. In some implementations, the controller **202** can be stored in the memory **237** of the computing device **200** and can be accessible and executable by the processor **235**. The controller **202** may be adapted for cooperation and communication with the processor **235** and other components of the computing device **200**.

The controller **202** sends and receives data, via the communication unit **241**, to and from one or more of the client device **115**, the data server **120**, the navigation server **101** and the mobile computing system **135** depending upon where the navigation application **109** is stored. For example, the controller **202** receives, via the communication unit **241**, data describing a query result from the data server **120** and sends the query result to the search module **208**. In another example, the controller **202** receives graphical data for providing a user interface to a user from the user interface module **214** and sends the graphical data to the client device **115** or the mobile computing system **135**, causing the client device **115** or the mobile computing system **135** to present the user interface to the user.

In some implementations, the controller **202** receives data from other components of the navigation application **109** and stores the data in the storage device **245**. For example, the controller **202** receives graphical data from the user interface module **214** and stores the graphical data in the storage device **245**. In some implementations, the controller **202** retrieves data from the storage device **245** and sends the retrieved data to other components of the navigation application **109**. For example, the controller **202** retrieves data describing a zone of relevance from the storage **245** and sends the data to the search module **208**.

The map module **204** can be software including routines for matching a location on a map. In some implementations, the map module **204** can be a set of instructions executable by the processor **235** to provide the functionality described below for matching a location on a map. In some implementations, the map module **204** can be stored in the memory **237** of the computing device **200** and can be accessible and executable by the processor **235**. The map module **204** may be adapted for cooperation and communication with the processor **235** and other components of the computing device **200**.

In one embodiment, the map module **204** receives data describing a current location associated with a user. For example, the map module **204** receives data describing a current location associated with a user from a global positioning system (GPS) installed on a client device **115** or a mobile computing system **135** that is operated by the user. In one embodiment, the map module **204** retrieves data describing a local map associated with the current location of the user from a data server **120**. For example, the map module **204** sends a request for a local map to the mapping application **122** via the network **105** and receives data describing the local map from the mapping application **122**.

The map module **204** matches the current location on the local map and determines a road type associated with the current location of the user. For example, the map module **204** pinpoints the current location on the local map and determines a road type associated with the current location. Example road types include, but are not limited to, a highway, a local street, a parking lot, a trail, a bridge, a tunnel or a private road, etc. Other example road types are possible. In one embodiment, the map module **204** sends data describing the road type to the status module **206**. In another embodiment, the map module **204** stores the data describing the road type in the storage **245**.

The status module **206** can be software including routines for determining a travel status associated with a user. In some implementations, the status module **206** can be a set of instructions executable by the processor **235** to provide the functionality described below for determining a travel status associated with a user. In some implementations, the status module **206** can be stored in the memory **237** of the computing device **200** and can be accessible and executable by the processor **235**. The status module **206** may be adapted for cooperation and communication with the processor **235** and other components of the computing device **200**.

In one embodiment, the status module **206** receives data describing one or more of a current location, a travel speed, a current travel route and a travel direction associated with a user from a GPS installed on a client device **115** or a mobile computing system **135** operated by the user. Example travel directions include, but are not limited to, a direction heading south, a direction heading north, a direction heading southeast, a direction entering a highway, a direction exiting from a highway, etc. Other example travel directions are possible. In one embodiment, the status module **206** receives data describing a road type associated with the current location from the map module **204**.

The status module **206** determines a travel status associated with the user. A travel status is data describing a state of travel associated with a user. In one embodiment, a travel status includes one or more of the current location, the travel speed, the travel route, the travel direction and the road type associated with the user. For example, a travel status indicates that a user is at the start of travel because an engine of a vehicle operated by the user is just turned on and the travel speed is zero. In another example, a travel status indicates that a user takes a left turn and moves forward in a new travel direction. In yet another example, a travel status indicates a user is traveling on a highway in a southbound direction with a speed of 65 miles per hour. In yet another example, a travel status indicates that a user stops at an intersection of two roads. In yet another example, a travel status indicates that a user is at the end of travel because the travel speed is zero and an engine

of a vehicle operated by the user is just turned off. Other example travel statuses are possible.

In one embodiment, the status module **206** sends data describing the travel status to the zone creator **207**. In another embodiment, the status module **206** stores data describing the travel status in the storage **245**.

The zone creator **207** can be software including routines for creating a zone of relevance associated with a user. In some implementations, the zone creator **207** can be a set of instructions executable by the processor **235** to provide the functionality described below for creating a zone of relevance associated with a user. In some implementations, the zone creator **207** can be stored in the memory **237** of the computing device **200** and can be accessible and executable by the processor **235**. The zone creator **207** may be adapted for cooperation and communication with the processor **235** and other components of the computing device **200**.

A zone of relevance is a geographic area or a combination of geographic areas relevant to a user. For example, a zone of relevance is a geographic area or a combination of geographic areas extended forward from a current location associated with a user. In one embodiment, a zone of relevance includes one or more regions. A region is a sub-area from the zone of relevance. In one embodiment, a region is a sub-area associated with a current location of a user. For example, a region is a sub-area extended forward from a current location of a user. In one embodiment, a region is a sub-area having a triangular shape, a rectangular shape, a circular shape or any other geometry shape. In another embodiment, a region is formed by a combination of geographic areas having various geometry shapes. For example, a region is formed by a combination of circular geographic areas as illustrated in FIG. **7**E. Example regions in zones of relevance are illustrated with reference to FIGS. **7**A-**7**F.

In one embodiment, the zone of relevance includes a front region, a left region and a right region. A front region can be a region where a user is predicted to travel forward from a current location. For example, a front region is a region aligned with a travel direction associated with a user. In another example, if a user is traveling on a highway, a front region is a region along the highway that is extended ahead from the current location of the user. When facing towards the travel direction associated with the user, a left region is a region on the left hand side of the front region and a right region is a region on the right hand side of the front region.

Turning to FIG. **7**A, a zone of relevance that includes a front region **704**, a left region **702** and a right region **706** is illustrated according to some examples. The front region **704**, the left region **702** and the right region **706** each have a triangular shape (e.g., an isosceles triangular shape). FIG. **7**A illustrates a current location **724** and a travel direction **725** associated with the user.

In some embodiments, a centerline is a line that divides a region into two equal parts. For example, a centerline **708***a* divides the left region **702** into two equal parts, a centerline **708***b* divides the front region **704** into two equal parts, and a centerline **708***c* divides the right region **706** into two equal parts.

In some embodiments, a regional angle is an angle formed by a centerline and a boundary line of the region, where the boundary line extends from the current location associated with the user. FIG. **7**A illustrates a regional angle **710***a* of the left region **702**, a regional angle **710***b* of the front region **704** and a regional angle **710***c* of the right region **706**.

In some embodiments, a regional length is a distance from the current location associated with the user to a bottom boundary of the region. For example, a regional length is a distance from the current location to the bottom side of the triangular region. FIG. **7**A illustrates a regional length **720***a* of the left region **702**, a regional length **720***b* of the front region **704** and a regional length **720***c* of the right region **706**.

In some embodiments, an angle offset associated with two regions is an angle between two centerlines of the two regions. FIG. **7**A illustrates an angle offset **712***a* associated with the left region **702** and the front region **704** and an angle offset **712***b* associated with the front region **704** and the right region **706**.

Turning back to FIG. **2**, in one embodiment the zone creator **207** receives data describing a travel status associated with a user from the status module **206**. The zone creator **207** determines a zone of relevance including one or more regions for the user based on the travel status of the user. For example, the zone creator **207** determines a size of the zone of relevance (e.g., a size of a geographic area specified by the zone of relevance) based on one or more of the current location, the travel speed, the travel direction, the road type and one or more travel preferences associated with the user.

In some implementations, the zone creator **207** determines a number of regions, a size for each region and a distance between two regions based on the travel status. For example, the zone creator **207** determines one or more of (1) a regional angle for each region, (2) a regional length for each region and (3) an angle offset between two adjacent regions based on one or more of the current location, the road type, the travel direction and the travel speed, etc. In some implementations, each region has the same regional angle and the same regional length, and each two adjacent regions have the same angle offset. In some other implementations, each region has a different regional angle and a different regional length, and each two adjacent regions have a different angle offset.

The zone creator **207** is capable of continuously and dynamically configuring the zone of relevance to accommodate updates on the travel speed, the road type and the travel direction, etc., as the user travels forward. For example, assume the zone creator **207** generates a front region, a left region and a right region for the zone of relevance. At the start of travel, the zone creator **207** generates: (1) a first regional angle and a first regional length for the front region; (2) a second regional angle and a second regional length for the left region; (3) a third regional angle and a third regional length for the right region; (4) a first angle offset between the front region and the left region; and (5) a second angle offset between the front region and the right region. The zone of relevance formed by the front region, left region and right region covers a widespread geographic area extended forward from the user's current location (e.g., a widespread geographic area extended forward on the user's travel direction).

As the user moves forward, the zone creator **207** gradually narrows down the zone of relevance and elongates the zone of relevance to be focused on the travel direction by one or more of: (1) reducing the first regional angle and/or increasing the first regional length for the front region; (2) reducing the second regional angle and/or increasing the second regional length for the left region; (3) reducing the third regional angle and/or increasing the third regional length for the right region; (4) reducing the first angle offset between the front region and the left region; and (5) reducing the second angle offset between the front region and the right region.

If the user enters a road where available directional choices are limited (e.g., a highway), the zone creator **207** further narrows down the zone of relevance and elongates the zone of relevance to be even more focused on the user's travel direction by further: (1) reducing the first regional angle and/or

increasing the first regional length for the front region; (2) reducing the second regional angle and/or increasing the second regional length for the left region; (3) reducing the third regional angle and/or increasing the third regional length for the right region; (4) reducing the first angle offset between the front region and the left region; and/or (5) reducing the second angle offset between the front region and the right region. In this case, the zone of relevance is concentrated on a route determined by the road (e.g., a route defined by the highway). The zone of relevance may also include intersections close by the route.

In one embodiment, the zone creator **207** matches each generated region into one or more sub-regions, where each sub-region is located either completely or partially within the respective region. The sub-region can be of a rectangular shape, a square shape, a circular shape or any other shape. A sub-region with a circular shape that is located at least partially within a region is referred to as a regional circle of the region. In some instances, the zone creator **207** matches each generated region to one or more regional circles, where each regional circle is located either completely or partially within the respective region. For example, the zone creator **207** determines one or more circle centers and one or more radii for one or more regional circles in each region, where the one or more regional circles are defined by the one or more circle centers and the one or more radii. The matching process between a region and one or more regional circles is described below with reference to FIGS. **5**-**6**C.

In some implementations, the one or more regional circles have increasing radii. The one or more regional circles have circle centers located on the centerline of the respective region. In some other implementations, some regional circles have the same radii, and some regional circles have circle centers not located on the centerline of the respective region. In one embodiment, the regional circles can be overlapping circles. For example, a regional circle can be overlapping with another adjacent regional circle in the same region. Example regions with overlapping regional circles are illustrated in FIG. **7**E. In another embodiment, the regional circles can be non-overlapping circles. For example, a regional circle does not overlap with another adjacent regional circle in the same region.

In one embodiment, the zone creator **207** creates a zone of relevance that includes one or more regions (e.g., a left region, a front region and a right region) with each region being mapped to one or more regional circles as described above. The zone creator **207** sends data describing the zone of relevance including all the regional circles in all the regions to the search module **208**. In one embodiment, the zone creator **207** stores the data describing the zone of relevance in the storage **245**.

The search module **208** can be software including routines for searching one or more data sources to retrieve a query result matching a query. In some implementations, the search module **208** can be a set of instructions executable by the processor **235** to provide the functionality described below for searching one or more data sources to retrieve a query result matching a query. In some implementations, the search module **208** can be stored in the memory **237** of the computing device **200** and can be accessible and executable by the processor **235**. The search module **208** may be adapted for cooperation and communication with the processor **235** and other components of the computing device **200**.

A query result is a search result matching a query. For example, a query result matches a zone of relevance specified by a query. In another example, a query result includes one or more of a road map, traffic information, road construction information, accident reports, locations of refreshment services, gas stations, tourist places, events (e.g., sport events), weather conditions, the user's historical travel data and any other data related to the zone of relevance.

In one embodiment, the search module **208** receives data describing a zone of relevance from the zone creator **207**. The search module **208** generates a query for the zone of relevance and searches one or more data sources to retrieve a query result that matches the query. Example data sources include, but are not limited to, the navigation server **101**, the mobile computing system **135** and one or more data servers **120**. For example, the search module **208** searches the storage device **144** in the mobile computing system **135** to retrieve the user's historical travel data related to the zone of relevance. In another example, the search module **208** searches one or more data servers **120** to retrieve one or more of real-time traffic updates, locations of gas stations, weather condition updates, etc., related to the zone of relevance. The search module **208** sends the query result to the processing module **210**.

In one embodiment, the search module **208** receives data describing a zone of relevance that includes one or more regions, where each region is mapped to one or more regional circles. The search module **208** generates one or more circle queries for the zone of relevance, with each circle query corresponds to one regional circle. A circle query is a query used to retrieve a query result that matches a regional circle. The search module **208** searches one or more data sources to retrieve one or more query results using the one or more circle queries. Each query result corresponds to one of the circle queries and matches a regional circle associated with the respective circle query. For example, a query result corresponding to a circle query includes one or more of traffic information, locations of refreshment services, gas stations, tourist places, events, weather conditions, the user's historical travel data and/or any other data matching a regional circle related to the circle query.

In one embodiment, the search module **208** stores the one or more query results in the storage **245**. In another embodiment, the search module **208** sends the one or more query results to the processing module **210**.

The processing module **210** can be software including routines for processing one or more query results. In some implementations, the processing module **210** can be a set of instructions executable by the processor **235** to provide the functionality described below for processing one or more query results. In some implementations, the processing module **210** can be stored in the memory **237** of the computing device **200** and can be accessible and executable by the processor **235**. The processing module **210** may be adapted for cooperation and communication with the processor **235** and other components of the computing device **200**.

In one embodiment, the processing module **210** receives one or more query results from the search module **208** and processes the one or more query results. In some implementations, the processing module **210** filters the one or more query results to remove duplicate data (e.g., duplicate traffic reports, duplicate weather forecasts, etc.). In some implementations, the processing module **210** filters the one or more query results to remove data related to a direction opposite to the user's travel direction. For example, assume a user travels on a highway in a southbound direction. The processing module **210** filters the query results to remove traffic information, road construction information, accident reports, etc., that only impact traffic flow in a northbound direction of the highway.

The processing module **210** generates zone information relevant to the user based on the processed query results. For

example, the processing module **210** combines the one or more filtered query results to generate zone information relevant to the user. Zone information is any information related to a zone of relevance associated with a user. In one embodiment, the zone information matches the zone of relevance associated with the user. For example, the zone information matches one or more regional circles in one or more regions in the zone of relevance. For example, the zone information includes one or more of traffic information (e.g., real-time traffic updates, accident reports, current traffic state in the zone of relevance), road construction information, locations of refreshment services, gas stations, tourist places, events, weather conditions and the user's historical travel data related to the zone of relevance. The zone information may include other information related to the zone of relevance.

In one embodiment, the processing module **210** sends the zone information to the presentation module **212**. In another embodiment, the processing module **210** stores the zone information in the storage **245**.

The presentation module **212** can be software including routines for presenting zone information to a user. In some implementations, the presentation module **212** can be a set of instructions executable by the processor **235** to provide the functionality described below for presenting zone information to a user. In some implementations, the presentation module **212** can be stored in the memory **237** of the computing device **200** and can be accessible and executable by the processor **235**. The presentation module **212** may be adapted for cooperation and communication with the processor **235** and other components of the computing device **200**.

In one embodiment, the presentation module **212** receives zone information relevant to a user from the processing module **210**. The presentation module **212** provides the zone information to the user. For example, the presentation module **212** delivers the zone information to the client device **115** and/or the mobile computing system **135**, causing the client device **115** and/or the mobile computing system **135** to play the zone information to the user using a speaker system (not shown). In another example, the presentation module **212** instructs the user interface module **214** to generate graphical data for providing a user interface that depicts the zone information to the user.

The user interface module **214** can be software including routines for generating graphical data for providing user interfaces to users. In some implementations, the user interface module **214** can be a set of instructions executable by the processor **235** to provide the functionality described below for generating graphical data for providing user interfaces to users. In some implementations, the user interface module **214** can be stored in the memory **237** of the computing device **200** and can be accessible and executable by the processor **235**. The user interface module **214** may be adapted for cooperation and communication with the processor **235** and other components of the computing device **200**.

In some implementations, the user interface module **214** generates graphical data for providing a user interface that presents zone information to a user. The user interface module **214** sends the graphical data to a client device **115** and/or a mobile computing system **135**, causing the client device **115** and/or the mobile computing system **135** to present the user interface to the user.

In some implementations, the user interface module **214** generates graphical data for providing a user interface to a user, allowing the user to configure a zone of relevance. For example, the user interface allows the user to configure a number of regions, a size of each region and a shape of each region. The user interface module **214** may generate graphical data for providing other user interfaces to users.

Methods

FIG. **3** is a flowchart of an example method **300** for providing zone information to a user. In one embodiment, the controller **202** optionally receives **302** data indicating a start of travel associated with a user. For example, the controller **202** receives data indicating an engine of a vehicle operated by a user is turned on. The controller **202** receives **304** data describing one or more of a current location, a travel speed and a travel direction associated with the user. The controller **202** receives **306** map data describing a local map associated with the current location. The status module **206** determines **308** a travel status associated with the user including one or more of the current location, the travel speed, the travel direction and a road type associated with the current location. The zone creator **207** creates **310** a zone of relevance for the user based on the travel status. The search module **208** generates **311** a query for the zone of relevance. The search module **208** searches **312** one or more data sources to retrieve a query result matching the query. The processing module **210** processes **314** the query result to generate zone information relevant to the user. The presentation module **212** provides **316** the zone information to the user. The method **300** determines **318** whether the user is at the end of travel. If the user is at the end of travel, the method **300** ends. Otherwise, the method **300** moves to step **304**.

FIGS. **4**A and **4**B are flowcharts of another example method **400** for providing zone information to a user. Referring to FIG. **4**A, the controller **202** optionally receives **402** data indicating a start of travel associated with the user. The controller **202** receives **404** data describing one or more of a current location, a travel speed and a travel direction associated with the user. The controller **202** receives **406** map data describing a local map associated with the current location. The map module **204** determines **408** a road type associated with the current location by matching the current location to the local map. The status module **206** determines **410** a travel status associated with the user including one or more of the current location, the travel speed, the travel direction and the road type.

The zone creator **207** optionally determines **411** a number of regions to be included in a zone of relevance. The zone creator **207** determines **412** a regional angle and a regional length for each region based on the travel status. Optionally, the zone creator **207** determines **413** an angle offset between two adjacent regions based on the travel status. The zone creator **207** generates **414** one or more regions based on one or more of the number of regions, the regional angle for each region, the regional length for each region and the angle offset between two adjacent regions.

Referring to FIG. **4**B, the zone creator **207** determines **415** one or more circle centers and one or more radii for one or more regional circles in each region. The zone creator **207** matches **416** each region to the one or more regional circles. The zone creator **207** creates **418** a zone of relevance that includes the one or more regions, with each region being mapped to the one or more corresponding regional circles. The search module **208** generates **420** one or more circle queries for the zone of relevance, with each circle query corresponding to one regional circle. The search module **208** searches **422** one or more data sources to retrieve one or more query results using the one or more circle queries. Each query result matches one of the circle queries. The processing module **210** processes **424** the one or more query results to generate zone information relevant to the user. The presentation module **212** provides **426** the zone information to the user.

The method **400** determines **428** whether the user is at the end of travel. If the user is at the end of travel, the method **400** ends. Otherwise, the method **400** moves to step **404**.

FIG. **5** is a flowchart of an example method **500** for matching a region with one or more regional circles. In the following description, the example method **500** is described with reference to FIGS. **6**A-**6**C. In one embodiment, the zone creator **207** configures **502** a distance parameter (represented as "d") with an initialization value. For example, the zone creator **207** initializes the distance parameter "d" with a default value. A distance parameter is data representing a distance to an origin point on the centerline of the region. In some examples, the origin point is the current location of the user. The zone creator **207** determines **504** a radius (represented as "r") for a regional circle based on the distance parameter "d" and the regional angle (represented as "α") associated with the region. For example, the zone creator **207** determines the radius as:

$$r = \frac{d\sin\alpha}{1-\sin\alpha}$$

The zone creator **207** determines **506** a circle center for the regional circle as a point on the centerline that has a center distance equal to "d+r." A center distance is a distance between the circle center and the origin point. For example, a center distance is equal to "d+r." The zone creator **207** generates **507** the regional circle determined by the radius "r" and the circle center. The zone creator **207** determines **508** whether the center distance of the latest generated regional circle is equal to or greater than the regional length of the region. For example, the zone creator **207** determines whether "d+r" is equal to or greater than the regional length of the region.

If the center distance is less than the regional length (e.g., the center distance is neither equal to nor greater than the regional length), the zone creator **207** updates **510** the distance parameter "d." In one embodiment, the regional circles in the region are non-overlapping circles, and the zone creator **207** increases the value of the distance parameter "d" by adding the value of "2r" to the distance parameter "d" (e.g., "d" is updated to be "d+2r"). In another embodiment, the regional circles in the region are overlapping circles with an overlapping distance (represented as "d_p") on the centerline. An overlapping distance is a distance on the centerline where two adjacent regional circles overlap with each other. The zone creator **207** increases the value of the distance parameter "d" by adding the value of "2r−d_p" to the distance parameter "d" (e.g., "d" is updated to be "d+2r−d_p").

After updating the distance parameter "d," the zone creator **207** continues to generate additional regional circles for the region by repeating the operations **504**-**510** until the center distance "d+r" is equal to or greater than the regional length.

For example, referring to FIG. **6**A the zone creator **207** configures the distance parameter "d" with an initialization value "d_0" (e.g., d=d_0). A radius for a first regional circle **610** is illustrated as "r_0." As illustrated in FIG. **6**A,

$$\sin\alpha = \frac{r_0}{d_0 + r_0},$$

and the zone creator **207** determines the radius "r_0" for the first regional circle **610** as

$$r_0 = \frac{d_0\sin\alpha}{1-\sin\alpha}$$

The zone creator **207** determines a circle center (a center point **604**) for the first regional circle **610** as a point on the centerline **606** of the region, where a center distance between the center point **604** and the origin point **602** is equal to "d_0+r_0." The zone creator **207** generates the first regional circle **610** which is determined by the radius "r_0" and the center point **604**.

Because the center distance "d_0+r_0" is less than the regional length, the zone creator **207** continues to generate additional regional circles in the region. In one embodiment, the regional circles in the region are non-overlapping circles as illustrated in FIG. **6**B, and the zone creator **207** updates the distance parameter to be "$d_1=d_0+2r_0$," where the symbol "d_1" represents the updated distance parameter. In another embodiment, the regional circles in the region are overlapping circles with an overlapping distance "d_p" as illustrated in FIG. **6**C, and the zone creator **207** updates the distance parameter to be "$d_1=d_0+2r_0-d_p$."

In either embodiment illustrated in FIG. **6**B or FIG. **6**C, the zone creator **207** determines a radius (represented as "r_1") for a second regional circle **660** as

$$r_1 = \frac{d_1\sin\alpha}{1-\sin\alpha}.$$

The zone creator **207** determines a circle center (a center point **654**) for the second regional circle **660** as a point on the centerline **606** of the region, where a center distance between the center point **654** and the origin point **602** is equal to "d_1+r_1." The zone creator **207** generates the second regional circle **660** which is determined by the radius "r_1" and the center point **654**. If a center distance of the latest generated regional circle is neither equal to nor greater than the regional length, the zone creator **207** may continue to generate additional regional circles for the region by performing operations similar to those described above.

Graphic Representations

FIGS. **6**A-**6**C are graphic representations **600**, **650**, **670** illustrating a process to match a region to one or more regional circles according to some embodiments. FIGS. **6**A-**6**C are described above with reference to FIG. **5**, and the description will not be repeated here.

FIGS. **7**A-**7**F are graphic representations **700**, **730**, **740**, **750**, **760**, **770** illustrating various zones of relevance according to some embodiments. FIG. **7**A is described above with reference to FIG. **2**, and the description will not be repeated here. FIG. **7**B illustrates a left region **732**, a front region **734** and a right region **736** of a zone of relevance associated with a user at the start of travel according to one embodiment. FIG. **7**C illustrates a left region **742**, a front region **744** and a right region **746** of a zone of relevance configured according to a travel direction associated with a user according to one embodiment. FIG. **7**D illustrates a left region **752**, a front region **754** and a right region **756** of a zone of relevance associated with a user when the user travels on a freeway according to one embodiment. FIG. **7**E illustrates a left region **762**, a front region **764** and a right region **766** of a zone of relevance associated with a user when the user travels on a freeway according to one embodiment. Each region in FIG. **7**E is mapped to multiple regional circles **768**.

Referring to FIG. 7E, a zone of relevance with a left region **772**, a front region **778** and a right region **780** is illustrated. FIG. 7E also illustrates a current location **774** and a travel direction **775** associated with a user, a centerline **776***a* for the left region **772**, a centerline **776***b* for the front region **778** and a centerline **776***c* for the right region **780**. The left region **772**, the front region **778** and the right region **780** are of rectangular shapes.

In the above description, for purposes of explanation, numerous specific details are set forth in order to provide a thorough understanding of the specification. It will be apparent, however, to one skilled in the art that the disclosure can be practiced without these specific details. In other implementations, structures and devices are shown in block diagram form in order to avoid obscuring the description. For example, the present implementation is described in one implementation below primarily with reference to user interfaces and particular hardware. However, the present implementation applies to any type of computing device that can receive data and commands, and any peripheral devices providing services.

Reference in the specification to "one implementation" or "an implementation" means that a particular feature, structure, or characteristic described in connection with the implementation is included in at least one implementation of the description. The appearances of the phrase "in one implementation" in various places in the specification are not necessarily all referring to the same implementation.

Some portions of the detailed descriptions that follow are presented in terms of algorithms and symbolic representations of operations on data bits within a computer memory. These algorithmic descriptions and representations are the means used by those skilled in the data processing arts to most effectively convey the substance of their work to others skilled in the art. An algorithm is here, and generally, conceived to be a self consistent sequence of steps leading to a desired result. The steps are those requiring physical manipulations of physical quantities. Usually, though not necessarily, these quantities take the form of electrical or magnetic signals capable of being stored, transferred, combined, compared, and otherwise manipulated. It has proven convenient at times, principally for reasons of common usage, to refer to these signals as bits, values, elements, symbols, characters, terms, numbers or the like.

It should be borne in mind, however, that all of these and similar terms are to be associated with the appropriate physical quantities and are merely convenient labels applied to these quantities. Unless specifically stated otherwise as apparent from the following discussion, it is appreciated that throughout the description, discussions utilizing terms including "processing" or "computing" or "calculating" or "determining" or "displaying" or the like, refer to the action and processes of a computer system, or similar electronic computing device, that manipulates and transforms data represented as physical (electronic) quantities within the computer system's registers and memories into other data similarly represented as physical quantities within the computer system memories or registers or other such information storage, transmission or display devices.

The present implementation of the specification also relates to an apparatus for performing the operations herein. This apparatus may be specially constructed for the required purposes, or it may comprise a general-purpose computer selectively activated or reconfigured by a computer program stored in the computer. Such a computer program may be stored in a computer readable storage medium, including, but is not limited to, any type of disk including floppy disks, optical disks, CD-ROMs, and magnetic disks, read-only memories (ROMs), random access memories (RAMs), EPROMs, EEPROMs, magnetic or optical cards, flash memories including USB keys with non-volatile memory or any type of media suitable for storing electronic instructions, each coupled to a computer system bus.

The specification can take the form of an entirely hardware implementation, an entirely software implementation or an implementation containing both hardware and software elements. In a preferred implementation, the specification is implemented in software, which includes but is not limited to firmware, resident software, microcode, etc.

Furthermore, the description can take the form of a computer program product accessible from a computer-usable or computer-readable medium providing program code for use by or in connection with a computer or any instruction execution system. For the purposes of this description, a computer-usable or computer readable medium can be any apparatus that can contain, store, communicate, propagate, or transport the program for use by or in connection with the instruction execution system, apparatus, or device.

A data processing system suitable for storing and/or executing program code will include at least one processor coupled directly or indirectly to memory elements through a system bus. The memory elements can include local memory employed during actual execution of the program code, bulk storage, and cache memories which provide temporary storage of at least some program code in order to reduce the number of times code must be retrieved from bulk storage during execution.

Input/output or I/O devices (including but not limited to keyboards, displays, pointing devices, etc.) can be coupled to the system either directly or through intervening I/O controllers.

Network adapters may also be coupled to the system to enable the data processing system to become coupled to other data processing systems or remote printers or storage devices through intervening private or public networks. Modems, cable modem and Ethernet cards are just a few of the currently available types of network adapters.

Finally, the algorithms and displays presented herein are not inherently related to any particular computer or other apparatus. Various general-purpose systems may be used with programs in accordance with the teachings herein, or it may prove convenient to construct more specialized apparatus to perform the required method steps. The required structure for a variety of these systems will appear from the description below. In addition, the specification is not described with reference to any particular programming language. It will be appreciated that a variety of programming languages may be used to implement the teachings of the specification as described herein.

The foregoing description of the implementations of the specification has been presented for the purposes of illustration and description. It is not intended to be exhaustive or to limit the specification to the precise form disclosed. Many modifications and variations are possible in light of the above teaching. It is intended that the scope of the disclosure be limited not by this detailed description, but rather by the claims of this application. As will be understood by those familiar with the art, the specification may be embodied in other specific forms without departing from the spirit or essential characteristics thereof. Likewise, the particular naming and division of the modules, routines, features, attributes, methodologies and other aspects are not mandatory or significant, and the mechanisms that implement the specification or its features may have different names, divi-

sions and/or formats. Furthermore, as will be apparent to one of ordinary skill in the relevant art, the modules, routines, features, attributes, methodologies and other aspects of the disclosure can be implemented as software, hardware, firmware or any combination of the three. Also, wherever a component, an example of which is a module, of the specification is implemented as software, the component can be implemented as a standalone program, as part of a larger program, as a plurality of separate programs, as a statically or dynamically linked library, as a kernel loadable module, as a device driver, and/or in every and any other way known now or in the future to those of ordinary skill in the art of computer programming. Additionally, the disclosure is in no way limited to implementation in any specific programming language, or for any specific operating system or environment. Accordingly, the disclosure is intended to be illustrative, but not limiting, of the scope of the specification, which is set forth in the following claims.

What is claimed is:

1. A computer-implemented method comprising:

receiving data provided by one or more mobile computing systems configured to determine a current location and a travel speed associated with a user, the data describing the current location and the travel speed associated with the user;

determining a travel status associated with the user based on the current location and the travel speed, the travel status describing a current state of a journey of the user;

creating a zone of relevance for the user based on the travel status, the zone of relevance including one or more regions with each region being mapped to one or more regional circles, creating the zone of relevance including determining a regional angle and a regional length for each region based on the travel status, and generating the one or more regions based on the regional angle and the regional length;

generating one or more queries for the zone of relevance;

retrieving one or more query results that match the zone of relevance using the one or more queries;

processing the one or more query results to generate zone information relevant to the user; and

providing the zone information to the user.

2. The method of claim **1**, wherein creating the zone of relevance comprises:

determining one or more circle centers and one or more radii for the one or more regional circles in each region;

matching each region to the one or more corresponding regional circles that are determined by the one or more circle centers and the one or more radii; and

determining the zone of relevance including the one or more regions with each region being mapped to the one or more corresponding regional circles.

3. The method of claim **1**, wherein the one or more queries includes one or more circle queries with each circle query corresponding to one of the one or more regional circles in each region.

4. The method of claim **1**, wherein processing the one or more query results comprises:

filtering the one or more query results to remove duplicate data;

filtering the one or more query results to remove data related to a direction opposite to a travel direction associated with the user; and

combining the one or more filtered query results to generate the zone information relevant to the user.

5. The method of claim **1**, further comprising:

receiving data describing a travel direction associated with the user;

receiving data describing a local map associated with the current location;

matching the current location to the local map to determine a road type; and

wherein the travel status is further determined based on the road type and the travel direction.

6. The method of claim **1**, wherein the zone of relevance is configured based on at least one of a travel direction and a road type.

7. The method of claim **1**, wherein the one or more regions include a front region, a left region and a right region.

8. A computer program product comprising a non-transitory computer usable medium including a computer readable program, wherein the computer readable program when executed on a computer causes the computer to:

receive data provided by one or more mobile computing systems configured to determine a current location and a travel speed associated with a user, the data describing the current location and the travel speed associated with the user;

determine a travel status associated with the user based on the current location and the travel speed, the travel status describing a current state of a journey of the user;

create a zone of relevance for the user based on the travel status, the zone of relevance including one or more regions with each region being mapped to one or more regional circles, and to create the zone of relevance including determining a regional angle and a regional length for each region based on the travel status, and generating the one or more regions based on the regional angle and the regional length;

generate one or more queries for the zone of relevance;

retrieve one or more query results that match the zone of relevance using the one or more queries;

process the one or more query results to generate zone information relevant to the user; and

provide the zone information to the user.

9. The computer program product of claim **8**, wherein creating the zone of relevance comprises:

determining one or more circle centers and one or more radii for the one or more regional circles in each region;

matching each region to the one or more corresponding regional circles that are determined by the one or more circle centers and the one or more radii; and

determining the zone of relevance including the one or more regions with each region being mapped to the one or more corresponding regional circles.

10. The computer program product of claim **8**, wherein the one or more queries includes one or more circle queries with each circle query corresponding to one of the one or more regional circles in each region.

11. The computer program product of claim **8**, wherein processing the one or more query results comprises:

filtering the one or more query results to remove duplicate data;

filtering the one or more query results to remove data related to a direction opposite to a travel direction associated with the user; and

combining the one or more filtered query results to generate the zone information relevant to the user.

12. The computer program product of claim **8**, wherein the computer readable program when executed on the computer causes the computer to also:

receive data describing a travel direction associated with the user;

receive data describing a local map associated with the current location;

match the current location to the local map to determine a road type; and

wherein the travel status is further determined based on the road type and the travel direction.

13. The computer program product of claim **8**, wherein the zone of relevance is configured based on at least one of a travel direction and a road type.

14. A system comprising:

a processor; and

a memory storing instructions that, when executed, cause the system to:

receive data provided by one or more mobile computing systems configured to determine a current location and a travel speed associated with a user, the data describing the current location and the travel speed associated with the user;

determine a travel status associated with the user based on the current location and the travel speed, the travel status describing a current state of a journey of the user;

create a zone of relevance for the user based on the travel status, the zone of relevance including one or more regions with each region being mapped to one or more regional circles, and to create the zone of relevance including determining a regional angle and a regional length for each region based on the travel status, and generating the one or more regions based on the regional angle and the regional length;

generate one or more queries for the zone of relevance;

retrieve one or more query results that match the zone of relevance using the one or more queries;

process the one or more query results to generate zone information relevant to the user; and

provide the zone information to the user.

15. The system of claim **14**, wherein the instructions when executed cause the system to create the zone of relevance by:

determining one or more circle centers and one or more radii for the one or more regional circles in each region;

matching each region to the one or more corresponding regional circles that are determined by the one or more circle centers and the one or more radii; and

determining the zone of relevance including the one or more regions with each region being mapped to the one or more corresponding regional circles.

16. The system of claim **14**, wherein the instructions when executed cause the system to process the one or more query results by:

filtering the one or more query results to remove duplicate data;

filtering the one or more query results to remove data related to a direction opposite to a travel direction associated with the user; and

combining the one or more filtered query results to generate the zone information relevant to the user.

17. The system of claim **14**, wherein the instructions when executed cause the system to also:

receive data describing a travel direction associated with the user;

receive data describing a local map associated with the current location;

match the current location to the local map to determine a road type; and

wherein the travel status is further determined based on the road type and the travel direction.
